Overview

We have created a project through which users(developers) can give feedback to users(developers). User can see feedback given to them but they will not be able to see the name of the developer who has given feedback to them, that means the sender name is anonymous. In this, the first party can give feedback to the second party and the second party can also give feedback to the first party but they will not know the name of the sender. The Purpose of this is particularly helpful because it allows employees to speak their minds as freely as possible.

Goal

The main goal of this project is that the user will come to know their drawbacks and the area of improvement so that they can work on it.

Technologies Used

- Front end

- The entire front is built with [Angular 7](#). For CSS framework Bootstrap is used.

- Back end

- The backend is in [Node.js](#) with Express framework by using [PostgreSQL](#) as a database.

Technical Specification :

The technical specifications components of the NeoSCRUM website are listed and explained below.

1. Registration Page

The Register page has the following features.

NeoSCRUM

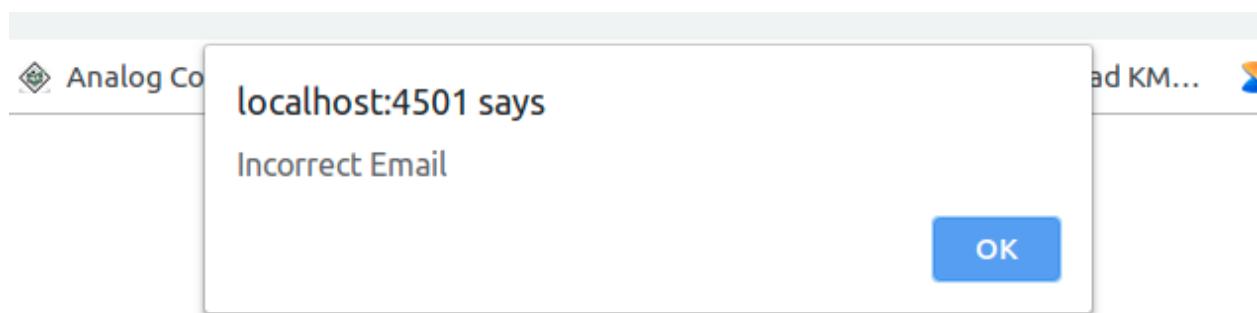

The screenshot shows a registration form titled 'Enter New Developer'. It contains three input fields: 'Employee Name *', 'Email *', and a file upload field labeled 'Choose file' with the placeholder 'No file chosen'. A blue 'Submit' button is at the bottom.

Enter New Developer	
Employee Name *	<input type="text"/>
Email *	<input type="text"/>
Choose file	No file chosen
<input type="button" value="Submit"/>	

The Login page has the following features.

- Input fields

There are three input fields name, email and profile image as shown in the figure. Validation is also done if the user enters invalid inputs. It will show error popup.

Enter New Developer

Employee Name *

Naveen Patel

Email *

23432

Choose file No file chosen

Submit

A screenshot of a web form titled "Enter New Developer". The form has two input fields: "Employee Name *" containing "Naveen Patel" and "Email *" containing "23432". Below these fields is a "Choose file" button followed by the text "No file chosen". At the bottom is a large blue "Submit" button.

- API to hit
POST api/register For user registration

- Work-Flow

As we know we have three input field `user_name`, `user_email`, and `profile_image` for user registration. Only the admin can register a new user. So whenever admin will insert the user data and press submit button, we will validate all the field that it is formatted or not, like `user_name` should be string, email id should be of proper format and `profile_image` should be of JPEG, JPG and PNG file format.

If any of the above fields is not correct, an error popup will be shown. But if all field filled correctly then we will hit registration API and at the backend side we are also validating all field by using JOI (npm package) and If the data is correct then we will get a success response from API. But if it is not correct then we will get a failure(error) response.

The unique thing is that we are not taking password while registering new user, we are generating it and sending the password to the email id of the user. For security reason, we are converting the password into the hashed format with the help of package bcrypt in backend and storing the hashed form in the database.

After successful registration, welcome mail automatically sent to the user (by using Sendmail npm package in the backend). It contains login credentials and login page's link.

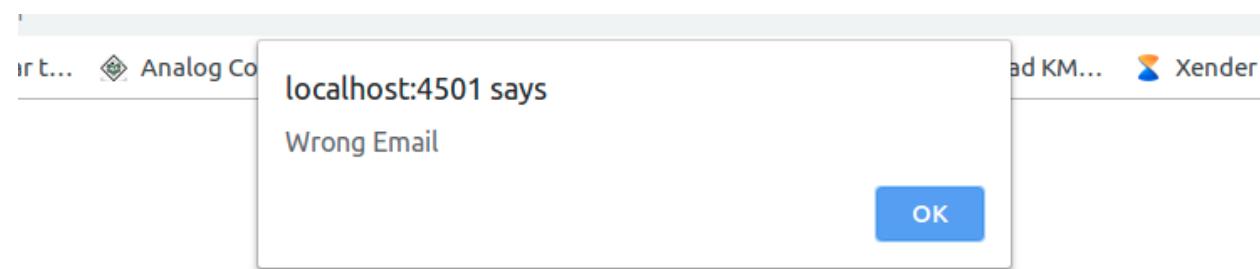

2. Login Page

NeoSCRUM

The diagram illustrates the NeoSCRUM Login page. At the top center is the word "Login". Below it are two input fields: "Email *" and "Password *". To the right of each input field is a horizontal line with an arrow pointing to a descriptive text box. The "Email *" field is associated with the text "Email input should use input reg". The "Password *" field is associated with the text "Password must be alphanumeric". Below the input fields is a blue "Login" button. To the left of the "Login" button is the URL "api/login".

The Login page has the following features.

- Input fields
 - a. There are two input fields email and password as shown in the figure. Validation is also done if the user enters invalid inputs. It will show error popup.

A screenshot of a login form. The title is 'Login'. There are two input fields: 'Email *' containing 'abc@|' and 'Password *' containing '*****'. To the right of the password field is a small icon. Below the inputs is a blue 'Login' button.

- API to hit
 - a. **POST api/login** For user login(also generate jwt token)

- Work-Flow

As we have two input field user_email, and password for user login. Where the user can log in by inserting their credentials and when user will press login button, first we will validate all fields and if all fields filled correctly then we will hit login API and at the backend side we are also validating all field by using JOI (npm package) and If the data is correct then we will get a success response with JWT token from API which is generated at backend by using JWT(npm package).

And we store the token in our browser's local storage so that we can use it in the next user-related API, but if the user credentials are not correct then we will get a failure(error) response form API and the error message will be related to validation error or verification error like if the user is not registered user or password not match then an error popup will be shown related to error.

3. Dashboard

The Dashboard page has the following features :

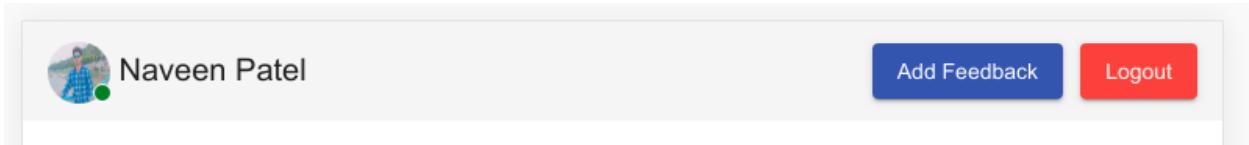

The screenshot shows a dashboard interface for 'Naveen Patel'. At the top, there's a user profile picture and name ('Naveen Patel'), followed by two buttons: 'Add Feedback' and 'Logout'. Below this, there are six feedback cards arranged in a 2x3 grid. Each card has a colored header bar (yellow, yellow, blue, red, blue, green) with the word 'Feedbacks' and 'in 6 hours'. The content of each card is as follows:

- Yellow Card:** 'Your program is very understandable' (sent by: Steve Jobs, posted on: 2nd Aug 2019)
- Yellow Card:** 'Learnet a lot from you:' (sent by: Satya Nadella, posted on: 2nd Aug 2019)
- Blue Card:** 'Can you help me to write the same awesome code as you did?' (sent by: Honey Singh, posted on: 2nd Aug 2019)
- Red Card:** 'I wasn't very impressed with those reports: you have to do better than that' (sent by: Nandan Nilekani, posted on: 2nd Aug 2019)
- Blue Card:** 'The tougher it is to measure individual performance, the tougher it is to evaluate it' (sent by: Arvind Kejriwal, posted on: 2nd Aug 2019)
- Green Card:** 'You really need to improve your communication skills.' (sent by: Arvind Kejriwal, posted on: 2nd Aug 2019)

- Feedback list

It contains a list of feedback which is given by other users. When feedback load it will animate the entire list. Angular Animation is also used on the loading of feedback.

- Navbar

The Navbar contains the following :

1. User information- User profile image and user name
2. Buttons (Add feedback) for adding feedback for other users and (logout) for account logout.

- API to hit

- GET [api/dashboard](#) For getting dashboard data(on oninit/on load)

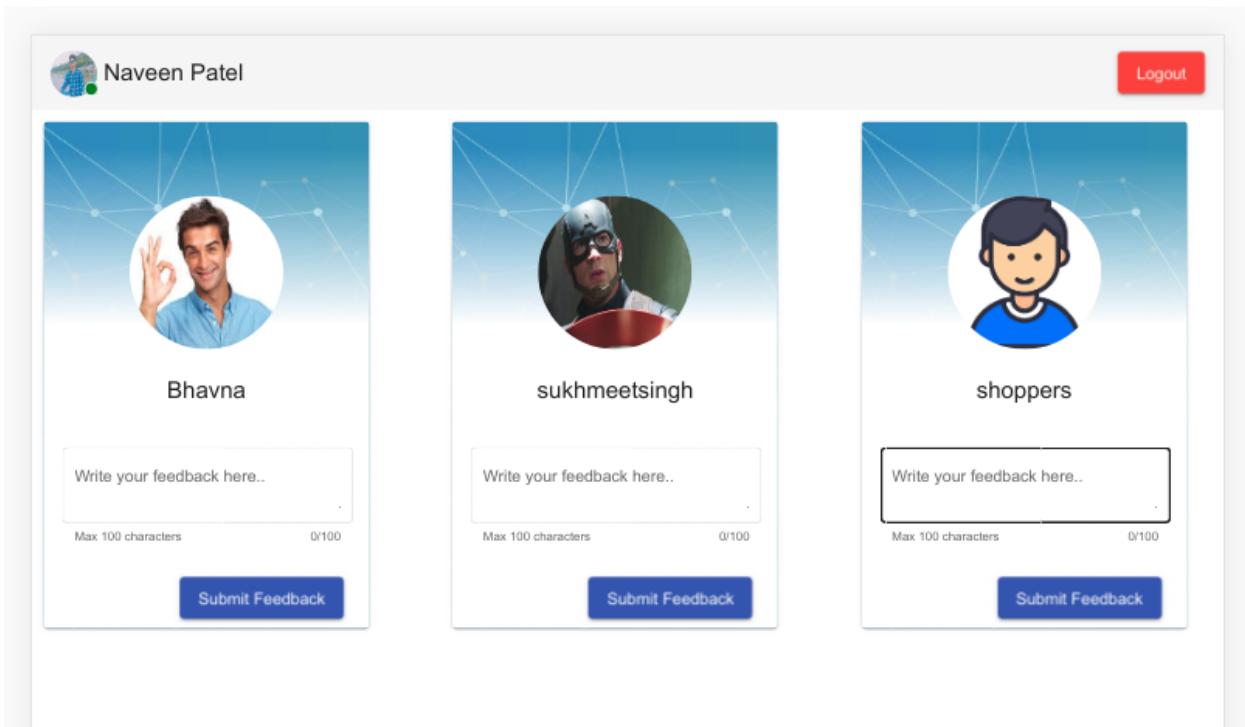

- Work-Flow

As we stored JWT token in our browser's local storage after successful login. Now we have to call dashboard API on on-init or on-load of dashboard page and where we need to send JWT token in the header because we are using JWT at the backend side for security purpose, so we verify the token at the backend side and if the token is valid then we will get a success response with dashboard data of user who is logged in.

The user's feedback is shown in the card and the user's details are shown in the navbar. Navbar contains Name, profile image of the user and two buttons in which one is for logout by which the user can logout and another one is for redirecting to add feedback page where the user can give feedback to other users but here we also need to send a token with API.

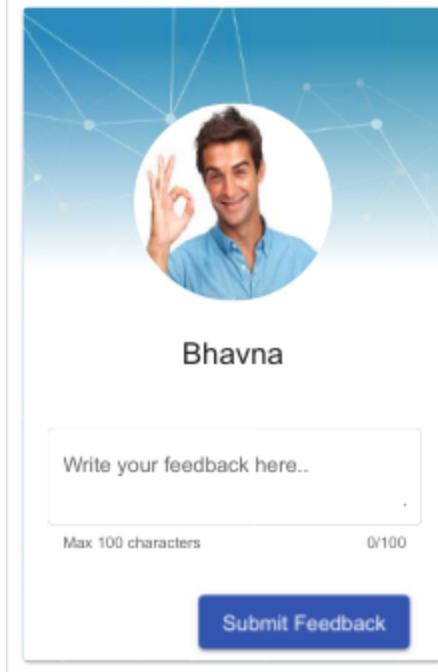

4. Add feedback page

The Add feedback page contains the following :

- Receiver list

It contains a list of receivers(also input fields) in which logged in user can give feedback for the receivers and list automatically update every Friday.

- Card

It contains information - the name of the receiver and profile image and input field for feedback.

- Submit Feedback

Whenever the user hits the submit button it calls API and saves feedback in the database and then the submit button will be disabled. And card automatically removed from the list.

- API to hit

- **GET api/Feedback** For getting a list of receiver
- **POST api/Feedback** For sending feedback

- Work-Flow

On this page, first we verify the token at the backend side and if the token is valid then we will get a success response with data. The data contain a list of user data to whom the user has to give feedback. It contains the name and profile image of users to whom feedback is to be sent.

Here we use cron job at the backend side. The cron job is a npm package that schedules a command or script on your server to run automatically at a specified time and date. So using this npm package we are generating a list of sender and receiver in such a way that no sender is repeated and the sender can't be a receiver for itself and also the same receiver can't be repeated twice in any sender's list.

Once sender (user) has given feedback to any receiver (user) so its card will be removed from screen as well update in the database by API so that sender can't give feedback again to the same user.

The unique thing is that after specified time cron job runs the server and hit api and mail automatically sent to the user. It contains receiver's name and login page's link. It also a type of reminder that reminds the user that you have to give feedback for the mentioned receiver.

Template

The zip of the website template is available [here](#)

Packages used for Angular 7 Project

- [Ngx-bootstrap](#)

ngx-bootstrap contains all core (and not only) Bootstrap components powered by Angular. So you don't need to include original JS components, but we are using markup and CSS provided by Bootstrap. Its official documentation is [here](#)

- [Moment.js](#)

Moment.js is a free and open-source **javascript library** that removes the need to use the native javascript Date object directly

- [Ngx-spinner](#)

An animated loading **spinner** for Angular 4+ is intended to inform the user that an operation is in progress.

- [angular material](#)

Angular Material is a UI component library for **Angular** JS developers. **Angular Material** components help in constructing attractive, consistent, and functional web pages and web applications while adhering to modern web design principles like browser portability, device independence, and graceful degradation.
